UNSEEN AND UNSPOKEN

The importance of identifying, diagnosing, and treating bipolar I disorder
What Is Bipolar I Disorder?

Bipolar I disorder is a mood disorder that causes sudden, major, and extended shifts in a patient’s mood (episodes). These episodes are classified as either depressive episodes or manic episodes.¹

Examples of signs and symptoms of bipolar I disorder

Bipolar Depression¹

- Sadness that doesn’t go away
- Changes in sleep patterns
- Changes in eating patterns
- Lack of pleasure in things they once enjoyed
- Unable to concentrate or perform routine tasks
- Suicidal thoughts

Bipolar Mania¹

- Overly energetic at odd hours
- Able to go without sleep
- Hyper-talkative
- Having racing thoughts
- Feeling giddy, irritable, or panicked for long periods of time
- Making impulsive or grandiose decisions

Manic and depressive symptoms can occur at the same time; this is known as bipolar I with mixed features.²

How is bipolar I diagnosed?

A person experiencing manic symptoms nearly all day, every day for a week, or whose symptoms lead to hospitalization, is considered to be having a manic episode. Just one manic episode is all it takes for a diagnosis of bipolar I disorder.¹

What are the risk factors for bipolar I?³

Highly predictive factors for identifying bipolar I in depressed patients:

- Family history of bipolar disorder
- Onset of illness in late teens to early 20s
- Seasonality of symptoms
- Numerous past episodes
- History of psychiatric hospitalization

- Simultaneous manic and depressive symptoms
- Abrupt mood swings or overly reactive
- History of treatment-resistant depression
- Antidepressant-activated mania
- History of suicide attempt

Patients with depressive symptoms that have not improved with antidepressants may suggest bipolarity³
Bipolar disorder is common and treatment is crucial

According to the National Institute of Mental Health (NIMH), an estimated 4.4% of adults in the U.S. will suffer from bipolar disorder, affecting men and women equally.4

Undiagnosed bipolar I is common in patients with depression

It has been documented that patients often provide unreliable or inaccurate self-reports of acute mood episodes, often due to lack of awareness or even embarrassment about their symptoms. Patients may not even view certain symptoms as problematic, all of which help explain the frequency with which bipolar disorder is misdiagnosed as depression.5

- On average, patients who were eventually diagnosed with bipolar disorder reported delays in diagnosis, with 1/3rd spending 10 years or more before being diagnosed5
- 25% of patients being treated for major depressive disorder in a primary care setting actually have bipolar disorder3
- More than half of bipolar patients experience a comorbid anxiety disorder which may complicate the diagnosis5

Treating bipolar I early is a priority

Delayed treatment or untreated bipolar disorder has been associated with a number of poor health outcomes and decreases in quality of life, including:

- Decreased job performance6
- Strained family relationships6
- Cardiovascular disease7

Earlier treatment showed improvement across a range of outcomes:

- Higher treatment response rate8
- Reduced episode duration8
- May slow progression of illness8

How are patients treated?

Despite not being FDA approved for bipolar I disorder, and carrying a warning of activating mania or hypomania in bipolar patients, antidepressants are the most commonly prescribed medication class9,10:

- 31% mood stabilizers
- 22% antipsychotics
- 47% antidepressants
The Mood Disorder Questionnaire (MDQ)

The MDQ is a proven and simple tool for screening bipolar disorder and can be administered by a clinician or self-administered by the patient.\(^3\),\(^11\),\(^12\)

**5 minutes to complete**  
15 questions

The MDQ has strong predictive power\(^3\),\(^11\),\(^12\)

In one of many validation studies, the MDQ was evaluated in 198 patients:

- Identified ~75% of bipolar patients\(^3\),\(^12\)
- Screened out bipolar disorder in 9 of 10 patients without the condition\(^3\),\(^12\)

Sensitivity  
0.73  
The MDQ correctly diagnosed bipolar disorder 73% of the time.\(^3\),\(^12\)

Specificity  
0.90  
The MDQ is highly accurate, with a low risk of false positive results.\(^3\),\(^12\)

The MDQ has been translated into 19 languages and cited in more than 600 publications\(^3\)

Bipolar mania—the unseen and unspoken symptoms

Identifying unapparent or unreported mania in your depressed patients can aid in making a correct diagnosis and inform your treatment approach. This screening tool was developed by a team of psychiatrists, researchers, and consumer advocates to aid in identifying patients with bipolar disorder. It has been extensively used and validated for over 20 years, and it can be administered by you or your staff, or self-administered by the patient, in approximately 5 minutes.

Using the MDQ

■ The MDQ is a brief self-report instrument that takes about 5 minutes to complete.\(^1\)

■ However, a positive screen is not a diagnosis of bipolar disorder. It is recommended to follow up by checking for recent symptoms, past symptoms, and family history.\(^2\)

Scoring MDQ Results\(^1\)

In order to screen positive for possible bipolar disorder, all three parts of the following criteria must be met:

■ “Yes” to 7 or more of the 13 items in Question 1 and

■ “Yes” to Question 2 and

■ An answer of “Moderate Problem” or “Serious Problem” to Question 3

Identifying Bipolar Disorder in Different Populations
